

Abstract of the Disclosure

METHOD AND APPARATUS FOR REDUCED ERROR CHECKING OF DATA RECEIVED BY A SERVER FROM A CLIENT

A server which service multiple clients according to a defined interface selectively determines whether to by-pass at least some error checks of client requests. Preferably, the client server interface uses a Java Database Connectivity (JDBC) API, there being a set of error checks associated with each type of request. For at least some error checks, the server selectively by-passes error checking. In the exemplary embodiment, the server by-passes error checking of certain error conditions at the client's request. Alternatively, the server might selectively by-pass error checking on the basis of the client's identity, or current server performance, or on a random or intermittent basis.
